In the treatment of brain metastases, Gamma Knife radiosurgery (GKRS) is currently the most effective method of controlling tumour growth. The most critical challenge in GKRS is target positioning, which can lead to a reduction in dose and thus loss of the desired effect. To mitigate this effect, a method of visualising the target from the radiosurgical plan is required, to allow for more accurate treatment planning. In this pilot study, we report the first use of three-dimensional (3D) printed models of brain tissue, for visualisation of the target in GKRS. The patient had multiple brain metastases from a metastatic melanoma and had previously received GKRS using standard stereotactic procedures. The brain metastases were visible from the computed tomography scans, however, the tumours were difficult to localise using routine stereotactic software and neuro-navigation. The 3D-printed model, consisting of soft tissue, tumour and surrounding vasculature, was created from the original CT scans using a freely available open-source software. In this model, the position of the tumour and vasculature were marked and the GKRS plans were simulated to demonstrate the advantages of the 3D-printed models. After the simulation, the GKRS plans were reviewed by a medical physicist and adjusted accordingly. The GKRS simulation with the models demonstrated more precise target positioning than previous efforts using standard stereotactic approaches alone. Furthermore 82157476af
